Abstract

Health information management (HIM) placements connect workplace learning with responsibilities for sensitive health information. This narrative review examined reported mentorship and supervision arrangements and developed an evidence-informed framework linking information governance to placement design. PubMed and the Education Resources Information Center (ERIC) were searched using broad population-and-placement strategies and support-term-filtered strategies, supplemented by Google Scholar searching, competency searching, reference-list searching, and hand-searching. The broad PubMed

search retrieved 20 eligible sources; the support-term-filtered search retrieved nine. Evidence was classified as core HIM placement evidence, related informatics placement evidence, or programme-level, preparation, and contextual evidence. Core placement sources described supervision, preceptorship, and placement management, with predominantly perceptual outcomes and barriers involving workload, preparation, technology, and access. No distinct mentoring intervention was identified in this review. Assessment methods in related health information technology and contextual training studies provide options for future evaluation, although they do not establish the effectiveness of HIM placement support. The proposed framework integrates accountable supervision and developmental mentorship across preparation, active placement, and closure. Seven governance-informed elements address task risk, access, data minimisation, review, auditability, assessment confidentiality, and escalation. The framework offers a structured basis for locally adapted placement planning and prospective evaluation. Limited database coverage, English-language selection, selective contextual searching, and evidence classification by one reviewer constrain completeness and transferability; the framework remains unvalidated.

Key Points

1. The health information management (HIM) placement literature describes supervision, preceptorship, and placement management. No distinct mentoring intervention was identified in this review. A support-term filter retrieved nine of 20 eligible PubMed sources, highlighting the value of broad population-and-placement searches for evidence synthesis in this field.

2. Many HIM placement tasks depend on controlled access to sensitive health information, although placements also include projects using de-identified data or simulated systems. Other health professions share stewardship responsibilities. The proposed contribution is to connect governance decisions explicitly to learning objectives, permitted tasks, review, and assessment in HIM placements.

3. The framework combines governance requirements with proposed educational safeguards across three placement phases. Objective assessment methods in related health information technology and contextual training studies offer candidates for future evaluation; they do not demonstrate that mentorship or supervision improves HIM placement outcomes. Programme coordinators can begin with documented roles, objectives, access plans, and escalation routes.

INTRODUCTION

Health information management (HIM) professionals combine information governance, data quality, classification, privacy, digital systems, and service improvement. Australian HIM competency standards address technical knowledge, ethical judgement and communication.[1] The American Health Information Management Association (AHIMA) curricula address information governance and information protection, while Saudi health-informatics benchmarking draws on International Medical Informatics Association (IMIA) recommendations.[2,3] These frameworks reflect related educational priorities within distinct qualifications and regulatory settings. Classroom teaching cannot reproduce every constraint of operational information environments.

'Placement' covers internships, professional practice experiences, practicums, and project-based work. HIM, health information administration (HIA), health information technology (HIT), health informatics, and medical informatics overlap in the retrieved literature but are treated as related, distinct populations. Australian HIM placements span hospitals, government, universities, and other organisations.[4] Medical-informatics practicums provide adjacent evidence about preparation, academic-service cooperation, and technical access.[5,6]

CC BY-NC 4.0 Licence • Copyright © 2026 EMJ

Placement alone does not ensure learning. A task may be authentic but poorly connected to programme outcomes, or a student may present without sufficient feedback or responsibility. Analysis of final-year placement proposals found 38 of 129 contained no explicit learning outcomes.[7] A mixed-methods evaluation in Ghana reported positive student experiences alongside inadequate supervision and inconsistent logbook use.[8] Remote HIM placements have shown that flexibility can coexist with technology problems and reduced informal interaction.[9] Attention therefore shifts from placement availability to the quality of support within the placement.

Mentorship is developmental, supporting reflection, belonging, identity, and career understanding. Supervision or preceptorship concerns assigned work, feedback, accountability, and assessment. Other health professions also steward confidential information. For many HIM tasks, however, decisions about record access, extraction, coding, and system use directly determine what the student can practise. Identifiable data are not the learning material in every placement; governance remains relevant to de-identified data, simulated systems, and service projects.

This review asks: what mentorship and supervision arrangements are reported in HIM placements, and how might information-governance principles inform their design? Billett's account of participation and Smith's placement-quality framework provide theoretical foundations.[10,11] The contribution is an explicit mapping of governance decisions to student tasks and educational support across preparation, active placement, and closure.

METHODS

PubMed and Education Resources Information Center (ERIC) via ProQuest were searched on 10 August 2026, without a lower date limit. Search A combined 'HIM', 'HIT', 'health informatics', 'medical informatics', and 'health information science' with placement terms. Search B added 'mentor*', 'supervis*', 'preceptor*', 'guidance', or 'feedback'. PubMed queries used the 'Title/Abstract [tiab]' field. ERIC queries used the 'NOFT (Anywhere except full text)' option, which searches bibliographic record fields, including titles, abstracts, and subject descriptors. Potentially eligible sources underwent full-text assessment against the eligibility criteria. Support terms were omitted from Search A because relevant arrangements may be described only in the full text. Supplementary File 1 provides database-specific strategies, search yields, study-level retrieval, and source routes.

Search A retrieved 68 PubMed and 12 ERIC records; Search B retrieved 19 and four, respectively. All 20 eligible PubMed sources were retrieved by Search A. Search B retrieved nine of the 20 eligible PubMed sources. The remaining 11 (55%), including the internship-monitoring Delphi study, were retrieved by Search A but not by Search B.[12] An identifier-restricted support-filter check corroborated the study-level comparison. This finding concerns retrieval within the included PubMed set; the small ERIC yield limits a comparable inference.

A supplementary PubMed competency search identified two sources. Google Scholar screening covered the first 100 relevance-ranked results per strategy in a signed-out session; no source was included solely through that route. Reference-list chaining, selected journal searches and professional websites supplied education, contextual mentorship, and governance sources. Contextual literature was selected purposively to inform support functions insufficiently described in HIM. Other health professions were not comprehensively searched. Supplementary File 1 documents source-specific routes and the available search records.

Eligible evidence concerned empirical findings, documentary analysis, or expert consensus about placement design, delivery, supervision, monitoring, assessment, or experience among HIM and related information disciplines. Preparation studies, programme-level evidence, and other-profession training were included as separately classified contextual

evidence when relevant to support design or measurement. Sources mentioning placement only in passing or through lexical coincidence were excluded. Selection was restricted to English-language publications; translation was not undertaken.

The database searches yielded 80 records with no cross-database duplicates. Full-text assessment supported inclusion of 22 database sources, including the e-HIM® (AHIMA, Chicago, Illinois, USA) Virtual Lab implementation report.[13] Two competency-search sources, 14 sources from reference-list and hand-searching, and two authoritative contextual sources completed the 40-reference evidence base. Table 1 presents eight core HIM/HIA placement sources in seven rows, combining Robinson and Nexhip because they analyse overlapping proposals. Supplementary File 2 classifies 24 sources in 23 rows, including related placements, preparation, programme-level evidence, and contextual training.

Evidence was classified by population, proximity to placement, design, measured outcome, and limitation, without a summary quality score or formal risk-of-bias tool. The Scale for the Assessment of Narrative Review Articles (SANRA) informed narrative-review reporting rather than study appraisal.[17] Explicit eligibility criteria, a decision ledger and separate evidence categories support methodological transparency.

Table 1: Core HIM placement evidence.

Source and setting	Design	Outcome type	Relevant finding	Limitation
Lewis,[14] Australia	Questionnaire	Student perceptions	Student feedback on placement value	Historical single programme; no comparator
Bah and Alanzi,[15] Saudi Arabia	120 internship reports	Documentary	Training opportunity differed by EHR environment	Three hospitals; no supervision measure
Branda,[16] USA	Six-preceptor qualitative study	Preceptor perceptions	Preparation and leadership barriers	Small preceptor sample; pandemic context
Prasad et al.,[9] Australia	Student and supervisor survey	Perceptions	Technology, schedules and regular communication	One programme; pandemic context
Robinson[4] and Nexhip,[7] Australia	Overlapping proposal analyses	Documentary	Placement tasks and objectives; 38 of 129 proposals lacked explicit learning outcomes	One university; proposals rather than observed supervision; overlapping corpus
Mensah et al.,[8] Ghana	Mixed methods	Perceptions and qualitative findings	Guidance and teamwork alongside supervision and logbook problems	Cross-sectional; no comparator
Barefield et al.,[13] USA	Two-programme implementation report	Student and site-director perceptions	Virtual laboratory integrated with professional practice experience	No controlled competency comparison; response denominators unclear

Core HIM placement evidence, showing design, outcome type and limitations. Eight sources appear in seven rows because Robinson and Nexhip analyse overlapping proposals. Related informatics placements, HIT preparation and assessment, programme surveys, expert consensus, and medical-student training are classified separately in Supplementary File 2.

EHR: electronic health record; HIM: health information management.

MENTORSHIP AND SUPERVISION IN HIM PLACEMENTS

Earlier HIM literature framed professional experience as a mechanism for integrating theory with practice. Marks and McIntosh described reflective thinking as central to meaningful placement learning,[18] and Lewis used post-placement questionnaires to obtain student feedback.[14] Bah and Alanzi compared 120 internship reports from three Saudi hospitals and found training opportunities differed by electronic health record environment.[15] Houser et al.[19] situated internships among several experiential learning approaches while noting resource constraints.

Workplace-learning theory informs the interpretation. Kolb's cycle, used by Mensah et al.,[8] links experience to reflection and conceptualisation. Billett emphasises the interaction between workplace opportunities and learner participation; Smith identifies quality dimensions including authenticity, alignment, support and preparation.[10,11] Health Information Management Association of Australia (HIMAA) explicitly addresses governance and health-information law and ethics.[1] The framework applies these educational and professional foundations to practical decisions about student access, permitted work, and review.

Contextual health-professions literature describes guidance, role modelling, feedback, psychosocial support, and career development.[20] Applying those functions to HIM is a proposal. Supervision additionally needs to define permissible work, check data handling, arrange help, and contribute assessment evidence where tasks involve sensitive records or consequential outputs.

Core HIM evidence describes preparation and support difficulties. Hospital preceptors reported limited preparation, engagement difficulties, inadequate leadership support, and little formal preceptor training.[16] Related HIT evidence offers expert-derived monitoring categories, covering students, supervisors, processes, evaluation, and communication; these categories have not established learning effects.[12] In health-informatics programmes, student internship perceptions and student-faculty differences are relevant but cannot establish support effectiveness in HIM.[21,22]

Adjacent evidence informs options rather than a preferred model. Penman et al.[23] examine near-peer placement mentoring and report potential benefits with limited evidence beyond self-report; Pope et al.[24] map supervision arrangements and find insufficient evidence favouring one model.[23,24] Germeroth et al.[25] describe mentorship attributes, programmes and heterogeneous outcomes across allied health. Programme surveys and expert benchmarking concern curriculum structure rather than observed supervision.[3,26] Public-health-informatics programmes provide contextual examples: Ke et al.[27] evaluated 149 paid interns across four cohorts, Rajamani et al.[28] reported a 692-student partnership programme, and Fenton and Mustata Wilson[29] described a diversity-focused programme. These are distinct from core HIM placements. Health-data-science internships and curriculum-implementation scholarship inform task preparation and curricular integration.[30,31]

The core HIM sources describe placement experience, supervision, preceptorship and management. No distinct, non-evaluative mentoring intervention was identified in this review. The synthesis differentiates these findings from related information-discipline and contextual evidence.

COMPONENTS, REPORTED OUTCOMES, AND CHALLENGES

Preparation Before the Placement

Preparation should connect competency standards to manageable objectives, outputs and observable behaviours.[1,7] Task-risk classification and review thresholds are proposed educational applications of governance principles, not controls tested by the placement studies. Expert preference for internship duration is contextual opinion rather than evidence for an optimal dose of support.[3] A placement agreement could link each objective to a permitted task, the

information needed, the expected output, and the criterion for successful completion. For example, a coding or data-quality task could specify the approved dataset, the review required before dissemination, and the form of evidence retained for assessment. This makes the proposed governance arrangements part of the learning plan.

The proposed role agreement assigns academic oversight and an independent student-concern route to the coordinator, operational access and performance review to the supervisor, and developmental conversation to the mentoring function. Where roles are combined, confidentiality limits and information that must enter assessment should be explicit. The agreement should also identify who can authorise changes to tasks or access and who responds when learning opportunities are insufficient. Students should know which conversations are developmental, which contribute to assessment, and which concerns require organisational action. Where one person fulfils several functions, the programme could provide a separate contact for concerns about assessment or support.

Supervisor preparation can be concise but should address programme outcomes, feedback, assessment, confidentiality, and escalation, since professional expertise alone may leave preceptors underprepared for an educational role.[16] Contextual evidence suggests peer-group mentoring may support supervisor development, although that literature did not establish student outcomes.[32]

Student orientation should cover conduct, information handling, systems, and help-seeking. Remote-placement and internship-site studies describe technology and opportunity constraints; they do not establish role-based access as an intervention.[9,15] An HIA implementation report describes virtual-lab integration with professional practice experience in two programmes, using perceptual rather than objective outcomes.[13] Simulation also supplies adjacent HIT preparation evidence.[33] Accessibility planning may consider disability, language, connectivity, and finance, informed by contextual diversity-focused programmes.[29]

Support During Active Placement

Observation and guided practice may precede increasing responsibility as performance allows, but staged autonomy should not become prolonged passive observation.

Operational check-ins can address tasks and access; a separate developmental conversation can address reasoning and career learning. Remote-placement evidence supports deliberate communication where informal contact is reduced.[9] Group or near-peer contact is a contextual option, not a substitute for accountable supervision.[23,24] Criterion-linked feedback, response arrangements and a midpoint review are proposed applications of placement-quality principles.[11]

Monitoring should support continuity without unnecessary data collection. Ghanaian logbook findings and expert-derived HIT categories inform its content, not its effectiveness.[8,12] The proposed application combines minimum necessary monitoring with a named reviewer and an auditable record of consequential decisions.

Assessment, Closure, and Reported Outcomes

Assessment can combine explicit supervisor criteria, an appropriate work product, and reflection. Lewis supports collecting student feedback.[14] The framework additionally proposes separate supervisor feedback, a mentoring transition conversation, and a documented placement-reuse decision.

Placement studies mainly report perceived knowledge, teamwork, exposure and engagement.[8,15,21,27] Remote HIM placements offer flexibility alongside technology and interaction barriers.[9] Preceptor benefits coexist with workload and weak organisational support.[16] A retrospective HIT graduate survey links internship participation with job placement, but cannot isolate an internship effect from prior characteristics.[34]

CC BY-NC 4.0 Licence • Copyright © 2026 EMJ

Objective measurement evidence requires a separate interpretation. In Iranian HIT assessment cohorts (15 students in 2022; 17 in 2023), Objective Structured Practical Examination means were 16.77 and 17.88, and real-environment observation means were 18.50 and 18.80; these are between-cohort descriptive differences, not within-person gains or a supervision effect.[35] Before internship, HIT simulation participants' mean scores for tasks involving Iran's electronic health record system changed from 16.33 to 18.80 (p=0.003), with completion time from 7.87 to 5.27 minutes (p=0.032); several tasks showed no significant change.[33] In contextual medical-student training, 27 third-year participants' record-keeping scores changed from 38.13 to 88.33/100 (p<0.001); 29 fourth-year comparison students scored 62.27, without a baseline comparison-group test.[36] In Tanzania, 27 practicum participants' knowledge means changed from 45.0 to 75.6, attitude means from 3.0 to 4.1, and practical-skills means from 2.5 to 4.0 (all p<0.001). Practical items included scenarios and self-assessment; the 27-person non-trained cohort was descriptive context only.[37] These studies offer assessment approaches, not evidence that HIM placement mentorship or supervision improves competence. Supplementary File 2 records outcomes, comparisons and numerical results and measurement limitations.

Positive satisfaction can coexist with uneven task quality, and completion of an authentic project does not show that learning generalises. Available evidence does not establish that mentorship causes improved placement outcomes, define an optimal contact frequency, or show that one supervision model is superior. Claims about patient care or organisational performance would exceed the evidence reviewed.

Barriers occur at several levels. Students may encounter unclear objectives, delayed access, or limited feedback; supervisors may lack educational preparation, protected time, or management support; and programmes struggle to maintain standards across diverse organisations while placements carry real institutional cost.[26] Privacy requirements may appropriately restrict access but narrow learning unless suitable tasks are planned.

An Information-Governance Framework for HIM Placements

The framework comprises seven governance-informed educational safeguards. Established principles support purpose limitation, necessary access, data minimisation, security, and accountability.[38,39] Task-risk categories, student-output review thresholds, and separate educational escalation translate these principles into proposed operational arrangements for placement support.

Task-risk classification and review thresholds identify student activities or outputs requiring supervisor review; their thresholds require local agreement and evaluation. Need-to-know access and minimum necessary information draw on Caldicott Principles 2–4, while General Data Protection Regulation (GDPR) Articles 5, 25, and 32 inform minimisation, accountability, and appropriate safeguards where applicable.[38,39] Auditability is applied here as a record of consequential educational decisions. Confidentiality-preserving assessment uses approved evidence, avoiding unnecessary disclosure; de-identification alone should not be assumed sufficient. Separate incident and student-concern routes are author-proposed safeguards for dependency on an assessor, without a claim of evaluated effectiveness.

Access is therefore one educational design variable alongside task authenticity, feedback, preparation, and assessment. It should support lawful, necessary learning activity, without treating live identifiable-data access as an entitlement or simulated work as inherently inadequate. Caldicott Principle 7 concerns sharing for individual care and does not independently authorise student access.[38] The framework requires an appropriate legal and organisational basis for each task.

Preparation agrees objectives, permitted work, access, review, evidence, and roles. Active placement combines accountable supervision with developmental mentorship, with explicit limits on confidentiality when functions overlap. Closure combines appropriate assessment evidence with feedback and improvement planning.

Table 2 distinguishes evidence about a problem, governing principles and author-proposed educational applications; its indicators measure delivery, not effectiveness. Figure 1 shows phase progression and dashed hypothesised pathways to proposed outcomes.

Local competency, accreditation, privacy, and organisational requirements take precedence. The Caldicott principles and GDPR are not universal regulatory codes. The USA Health Insurance Portability and Accountability Act of 1996 (HIPAA) guidance permits covered entities to shape trainee access policies for supervised training, demonstrating the need for jurisdiction-specific mapping rather than automatic transplantation.[40] Saudi Arabia and other settings require their own applicable law and institutional rules. Approved de-identified or simulated work may be appropriate when live access is unavailable.

Limitations include two-database coverage, English-language selection, purposive contextual searching, evidence classification by one reviewer and no formal risk-of-bias appraisal. Google Scholar's opaque relevance ranking and 100-result cap may omit older or less visible work. Search documentation is reported in Supplementary File 1; the unretained supplementary competency-query string limits reproducibility of that search. Core HIM evidence in Table 1 comes from Australia, Saudi Arabia, Ghana, and the USA; related and contextual studies extend the geographical range, but transferability requires local assessment. Overlapping Australian proposals do not constitute independent replication.[4,7] Most evidence is descriptive, and the controlled medical-student training comparison is contextual.[36] The framework's provenance establishes its conceptual basis rather than its effectiveness.

Prospective multi-site studies should compare specified support arrangements and account for task complexity, modality, duration, and supervisor experience. Outcomes could include objective competence, work quality, identity, employment transition, workload, cost, and equity. Related HIT assessment and contextual training methods are candidate tools requiring adaptation to HIM support research.[33,35-37] Process evaluation should examine delivery and context; qualitative work should examine help-seeking, power, and readiness for autonomy. For an initial pilot, coordinators could document objectives, roles, contact arrangements, approved access, and escalation using existing institutional procedures, then assess feasibility and workload before wider implementation. These are proposed starting steps, not a validated package. A pilot could use the delivery indicators in Table 2 to examine whether objectives were agreed, access or alternatives were ready, feedback occurred, and concerns reached the appropriate contact. Student and supervisor accounts could explain missed activities and the resources needed to deliver them. Feasibility findings should then guide refinement of the arrangement and selection of outcomes for a comparative study, rather than being interpreted as evidence of improved competence.

CONCLUSION

The retrieved HIM placement literature describes supervision, preceptorship, and management alongside workload, preparation, technology, and interaction barriers. No distinct mentoring intervention was identified through this review. Related programme and training studies inform possible arrangements and measurement, but should not be treated as evidence of effective HIM placement support.

The framework links governance decisions with educational support across preparation, active placement, and closure. It distinguishes established requirements from proposed educational applications and offers a structured basis for placement planning. Local adaptation and prospective evaluation are required to assess feasibility, effectiveness, cost, and comparative value. Assessment methods in related and contextual studies provide candidate tools for evaluation; their use to evaluate HIM mentorship or supervision was not identified in this review.

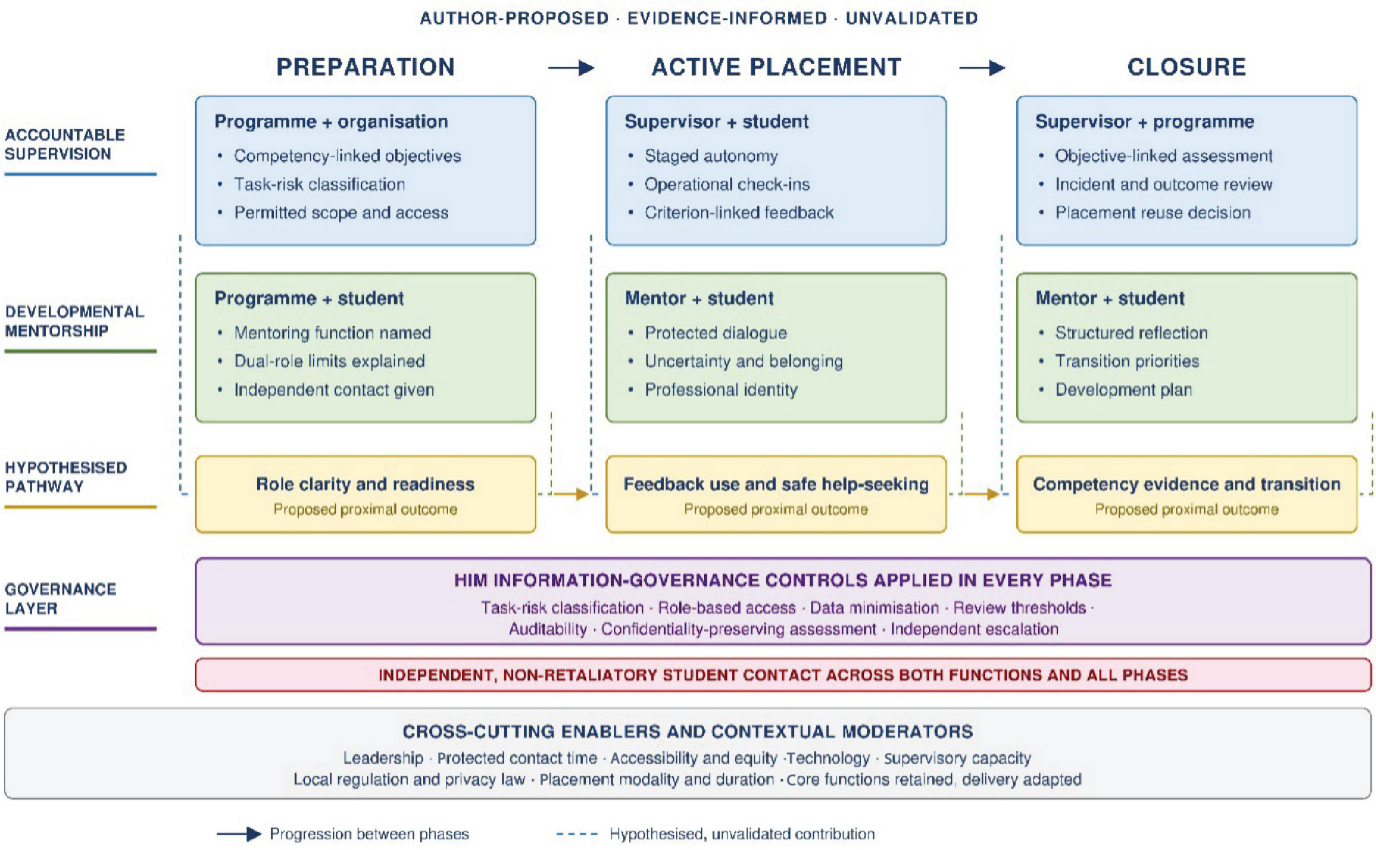
Table 2: Evidence to action matrix.

Phase	Proposed action	Provenance	Delivery indicator
Preparation	Agree objectives, outputs, and assessment evidence.	HIM standard and documentary planning evidence.[1,7]	Objectives and evidence agreed before start.
Preparation	Classify tasks and agree review thresholds.	Author proposal informed by access problems and applicable risk safeguards.[9,15,39]	Task categories and review thresholds recorded.
Preparation	Arrange necessary access or an approved alternative task.	Need-to-know and minimisation principles;[38,39] educational application proposed.	Access or approved alternative ready.
Preparation	Agree roles, confidentiality limits, orientation, and barrier follow-up.	Preceptor and contextual equity evidence;[16,29] dual-role safeguards proposed.	Roles and orientation recorded; barriers assigned.
Preparation	Use structured simulation where appropriate.	Related HIT preparation study, not placement support evidence.[33]	Completion or reason for omission recorded.
Active	Stage autonomy against task requirements and performance.	Author proposal; comparative support effect not established.	Autonomy decisions and reasons recorded.
Active	Plan operational contact and an alternative contact.	Remote HIM placement evidence;[9] response arrangements proposed.	Contact record and response expectations.
Active	Provide developmental conversation with explicit confidentiality limits.	Contextual mentorship sources;[20,23,25] HIM application proposed.	Contact delivered; independent route known.
Active	Provide criterion-linked feedback, improvement opportunity, and midpoint review.	Placement-quality framework;[11] schedule and application proposed.	Feedback and follow-up documented.
Active	Minimise monitoring data; record consequential decisions.	Logbook findings,[8] HIT consensus,[12] accountability, and minimisation;[39] application proposed.	Named reviewer and retrievable decision record.
Closure	Use approved assessment evidence and a transition conversation.	Necessary information and safeguards,[38,39] contextual mentoring;[20] application proposed.	Assessment meets local disclosure rules.
Closure	Collect separate feedback and decide on placement reuse.	Student feedback supported by Lewis;[14] supervisor feedback and reuse decision proposed.	Both feedback records and reuse decision.
All phases	Separate organisational incident reporting from student-concern escalation.	GDPR incident duties where applicable;[39] independent educational route proposed.	Routes and response responsibilities stated.

Evidence-to-action matrix for placement support. Provenance separates empirical or contextual evidence, applicable governance principles, and author-proposed educational applications. Process indicators document delivery rather than effectiveness. References to governance instruments do not establish that the proposed educational application has been tested.

GDPR: General Data Protection Regulation; HIT: health information technology; HIM: health information management.

Figure 1: Proposed framework for HIM placement support.



Author-proposed, evidence-informed, and unvalidated framework for mentorship and supervision in HIM placements. Solid horizontal arrows indicate phase progression. Dashed connectors link the supervision and mentorship strands to proposed proximal outcomes and indicate hypothesised contributions, not demonstrated causal effects.

HIM: health information management.
